Outline

What is harmony?

- Harmony arises when at least two notes sound at the same time
- Harmony induces tension and release patterns, that can be described by music theory and music cognition
- The internal structure of the chord has a large influence on the consonance or dissonance of a chord
- The surrounding context also has a large influence

A crash course on harmony theory I

A chord can be viewed as a group of tones that are separated by intervals of roughly the same size. Three factors are very important in how a chord is perceived:

A crash course on harmony theory I

A chord can be viewed as a group of tones that are separated by intervals of roughly the same size. Three factors are very important in how a chord is perceived:

- The intervals used in a chord, e.g. minor and major.
- The tone on which the chord has been built, called the root note.
- The surrounding chord sequence in which the chord occurs.

A crash course on harmony theory II

Models for musical harmony explain the harmonic progression in music:

- Based on the interval structure of a chord, we assign a class to a chord: Major, Minor, Dominant, ...
- Every tone in an octave can be used as a root note yielding scale degrees. These are typically numbered in Roman letters: I, II♭, II ... VI♯, VII.
- The function of a chord is determined by the surrounding chords in the sequence.

A crash course on harmony theory II

Models for musical harmony explain the harmonic progression in music:

- Based on the interval structure of a chord, we assign a class to a chord: Major, Minor, Dominant, ...
- Every tone in an octave can be used as a root note yielding scale degrees. These are typically numbered in Roman letters: I, II♭, II ... VI♯, VII.
- The function of a chord is determined by the surrounding chords in the sequence.

(Caveat: for simplicity we abstract from key and work in C major only. Therefore I corresponds to C, II to D, etc.)

Why are harmony models useful?

Having a model for musical harmony allows us to automatically determine the functional meaning of chords in the tonal context.

The model determines which chords "fit" on a particular moment in a song.

Why are harmony models useful?

Having a model for musical harmony allows us to automatically determine the functional meaning of chords in the tonal context.

The model determines which chords "fit" on a particular moment in a song. This is useful for:

- Musical information retrieval (find songs similar to a given song)
- Audio and score recognition (improving recognition by knowing which chords are more likely to appear)
- Music generation (create sequences of chords that conform to the model)

Representing harmony as a datatype

```
data Piece = Piece [Phrase]

data Phrase = P1 Ton Dom
            | P2 Ton

data Dom = D1 SDom Dom
         | D2 (Deg V DomCl)
         | D3 (Deg V MajCl)
         | ...

data Ton = T1 (Deg I MajCl)
         | T2 (Deg I MajCl) (Deg IV MajCl) (Deg I MajCl)
         | ...

data SDom = S1 (Deg II MinCl)
          | S2 (Deg IV MajCl)
          | ...
```

Handling degrees

First, we need degrees and chord classes at the type level:

```
data I; data II; ... data VII;
data Maj_Cl; data Min_Cl; data Dom_Cl; ...
```

We use them as phantom type parameters to Deg:

```
data Deg δ γ = Deg {chordRole  :: Int
                   , chordClass :: Class
                   , chordText  :: String}
data Class = Maj_Cl | Min_Cl | Dom_Cl ...
```

Parsing chord sequences

We now want to parse (textual) chord sequences into our datatype representing musical harmony:

```
data ParserMusic α    -- abstract
class Parse α where
  parse :: ParserMusic α
```

Parsing chord sequences

We now want to parse (textual) chord sequences into our datatype representing musical harmony:

```
data ParserMusic α    -- abstract
class Parse α where
  parse :: ParserMusic α
```

Most instances are trivial:

```
instance Parse Phrase where
  parse  =  P1 <$> parse <*> parse
        <|> P2 <$> parse
```

Parsing chord sequences

We now want to parse (textual) chord sequences into our datatype representing musical harmony:

```
data ParserMusic α    -- abstract
class Parse α where
  parse :: ParserMusic α
```

Most instances are trivial:

```
instance Parse Phrase where
  parse  =  P1 <$> parse <*> parse
        <|> P2 <$> parse
```

(So trivial that we do not write them; we use a generic parser.)

Parsing degrees

The interesting case is that for degrees:

```
instance (ToDegree δ, ToClass γ) ⇒ Parse (Deg δ γ) where
  parse = f <$> pChord deg clss where
    f (a, b, c) = Deg a b c
    deg = toDegree (⊥ :: δ)
    clss = toClass   (⊥ :: γ)
```

Parsing degrees

The interesting case is that for degrees:

```
instance (ToDegree δ, ToClass γ) ⇒ Parse (Deg δ γ) where
  parse = f <$> pChord deg clss where
    f (a, b, c) = Deg a b c
    deg = toDegree (⊥ :: δ)
    clss = toClass   (⊥ :: γ)

class ToDegree δ where toDegree :: δ → Int
class ToClass  γ where toClass  :: γ → Class

instance ToDegree I       ...   -- instances for all degrees
instance ToClass  Maj_CI  ...   -- instances for all classes

pChord :: Int → Class → ParserMusic (Int, Class, String)
pChord = ...
```

Increasing complexity

The model we presented so far is very simple and cannot account for:

Repeated chords $\underline{G_{Maj}\ G^7}\ C_{Maj}$

Increasing complexity

The model we presented so far is very simple and cannot account for:

Repeated chords $\underline{G_{Maj}\ G^7}\ C_{Maj}$

Diatonic secondary dominants $\underline{E_{min}\ A_{min}\ D_{min}}\ G^7\ C_{Maj}$

Universiteit Utrecht

[Faculty of **Science**
Information and Computing Sciences]

Increasing complexity

The model we presented so far is very simple and cannot account for:

Repeated chords $\underline{G_{Maj}\ G^7}\ C_{Maj}$

Diatonic secondary dominants $\underline{E_{min}\ A_{min}\ D_{min}}\ G^7\ C_{Maj}$

Chromatic secondary dominants $\underline{D^7}\ G^7\ C_{Maj}$

Increasing complexity

The model we presented so far is very simple and cannot account for:

Repeated chords $\underline{G_{Maj}\ G^7}\ C_{Maj}$

Diatonic secondary dominants $\underline{E_{min}\ A_{min}\ D_{min}}\ G^7\ C_{Maj}$

Chromatic secondary dominants $\underline{D^7}\ G^7\ C_{Maj}$

Minor key dominant borrowing $\underline{G_{min}}\ C_{Maj}$

Increasing complexity

The model we presented so far is very simple and cannot account for:

Repeated chords $\underline{G_{Maj}\ G^7}\ C_{Maj}$

Diatonic secondary dominants $\underline{E_{min}\ A_{min}\ D_{min}}\ G^7\ C_{Maj}$

Chromatic secondary dominants $\underline{D^7}\ G^7\ C_{Maj}$

Minor key dominant borrowing $\underline{G_{min}}\ C_{Maj}$

Tritone substitutions $\underline{A\flat^7}\ G^7\ C_{Maj}$

...

Handling repeated chords

Easy: adapt the Deg type and pChord:

```
data Deg δ γ = Deg {chordRole  :: Int
                   , chordClass :: Class
                   , chordText  :: [String]}
pChord :: Int → Class → ParserMusic (Int, Class, [String])
pChord = ...    -- adapted accordingly
```

Secondary dominants—datatype representation

Here the fun begins! Adapt the Deg type again:

$$\textbf{type}\ \mathsf{Deg}_{\mathsf{SD}}\ \ \delta\ \gamma = \mathsf{BDeg}_{\mathsf{SD}}\ \delta\ \gamma$$

$$\begin{aligned}&\textbf{data}\ \mathsf{BDeg}_{\mathsf{SD}}\ \delta\ \gamma\ \textbf{where}\\ &\quad \mathsf{Cons}\ ::\ \mathsf{BDeg}_{\mathsf{SD}}\ (\mathsf{Perf}_{\mathsf{V}}\ \delta)\ \mathsf{Dom}_{\mathsf{Cl}}\\ &\qquad\quad \rightarrow \mathsf{Deg}\ \delta\ \gamma \rightarrow \mathsf{BDeg}_{\mathsf{SD}}\ \delta\ \gamma\\ &\quad \mathsf{Base}\ ::\ \mathsf{Deg}\ \delta\ \gamma \rightarrow \mathsf{BDeg}_{\mathsf{SD}}\ \delta\ \gamma\end{aligned}$$

Secondary dominants—datatype representation

Here the fun begins! Adapt the Deg type again:

```
type Deg_SD δ γ = BDeg_SD δ γ

data BDeg_SD δ γ where
  Cons :: BDeg_SD (Perf_V δ) Dom_CI
       → Deg δ γ → BDeg_SD δ γ
  Base :: Deg δ γ → BDeg_SD δ γ

data Deg δ γ = Deg ...    -- as before

type family  Perf_V δ :: ⋆   -- computes the perfect fifth
type instance Perf_V I  = V
type instance Perf_V V = II
...
```

Secondary dominants—datatype representation

Here the fun begins! Adapt the Deg type again:

```
type Deg_SD δ γ = BDeg_SD δ γ (Su (Su (Su Ze)))
data BDeg_SD δ γ η where
  Cons :: BDeg_SD (Perf_V δ) Dom_CI η
       → Deg δ γ → BDeg_SD δ γ (Su η)
  Base :: Deg δ γ → BDeg_SD δ γ (Su η)

data Deg δ γ = Deg ...    -- as before

type family   Perf_V δ :: ⋆   -- computes the perfect fifth
type instance Perf_V I  = V
type instance Perf_V V  = II
...

data Ze      -- type level zero
data Su η    -- type level successor
```

Secondary dominants—instances

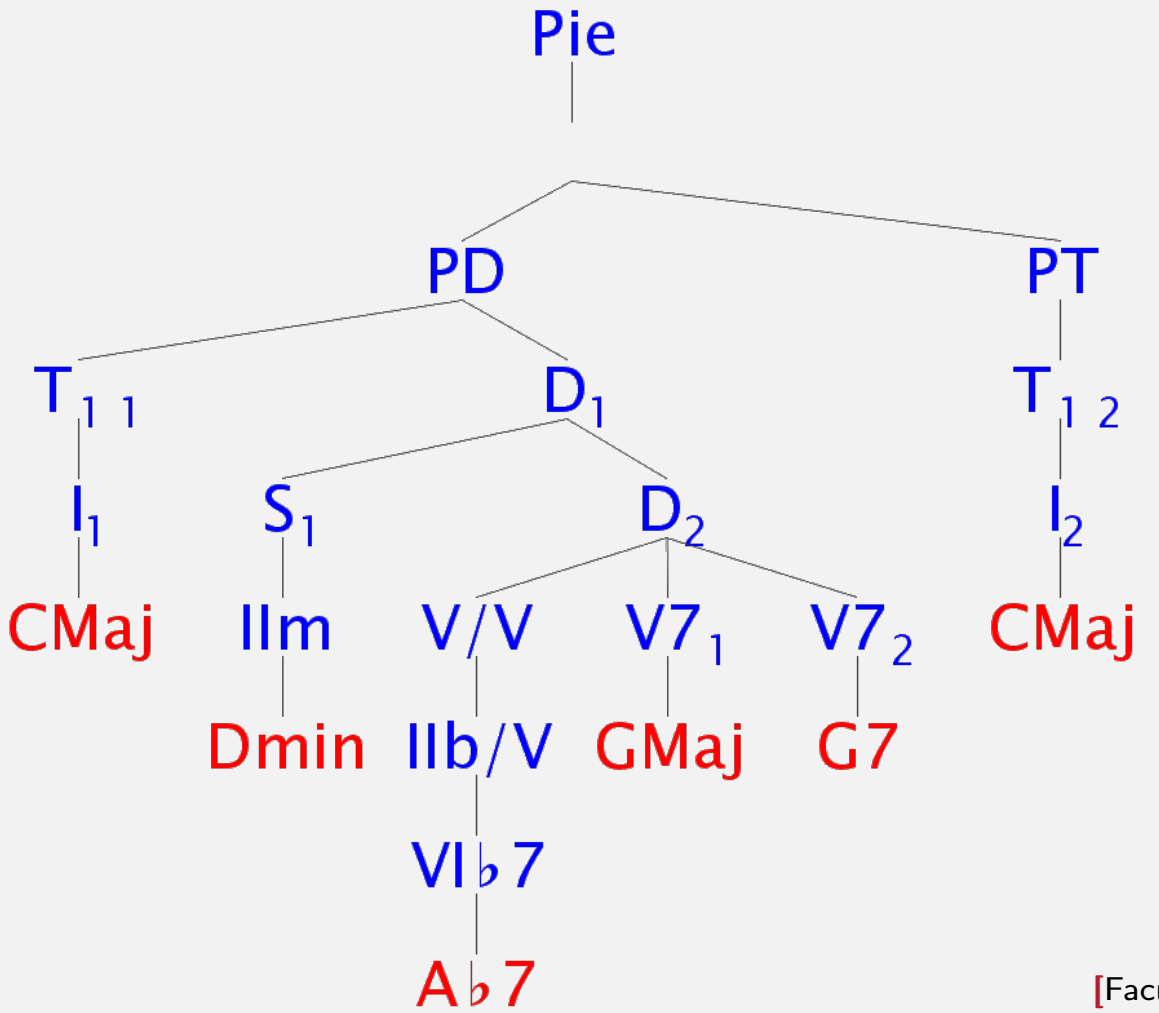
We also need an instance of Parse for $\mathsf{BDeg}_{\mathsf{SD}}$:

```
instance  (  Parse (Deg δ γ)
          ,  Parse (BDeg_SD (Perf_V δ) Dom_CI η      ))
          ⇒  Parse (BDeg_SD δ          γ      (Su η)) where
  parse  =   Base <$> parse
         <|> Cons <$> parse <*> parse
```

The code for parse is trivial, but the instance head is not.

Example

Parsing the sequence C_{Maj} D_{min} $A\flat^7$ G_{Maj} G^7 C_{Maj}:



Universiteit Utrecht

Information and Computing Sciences]

Summary

What we have so far:

- A model for musical harmony as a Haskell GADT
- The datatypes can change, the code does not have to:
  - Generic parser
  - Generic pretty-printer
  - Generic enumerator (automatically generate valid harmonic sequences)
- When chords do not fit the model: error correction

What we are working on:

- A similarity measure for our musical structures (or a generic diff?)

Limitations

- Performance:
  - Type checking: exponential on η
  - At runtime: grammar ambiguity
- Model:
  - Deal with minor keys
  - Modulations
